## - Solutions to Exercises

17.1 a. $\quad \mathrm{BaSO}_{4}(\mathrm{~s}) \quad \leftarrow \rightarrow \mathrm{Ba}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) \quad \mathrm{K}_{\text {sp }}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]$
b. $\quad \mathrm{Fe}(\mathbf{O H})_{3}(\mathrm{~s}) \quad \longleftrightarrow \rightarrow \mathrm{Fe}^{3+}(\mathrm{aq})+\mathbf{3 O H}^{-}(\mathrm{aq}) \quad \mathrm{K}_{\text {sp }}=\left[\mathrm{Fe}^{3+}\right]\left[\mathrm{OH}^{-}\right]^{3}$
c. $\quad \mathbf{C a}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s}) \leftarrow \rightarrow 3 \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{PO}_{4}{ }^{3-}(\mathrm{aq}) ; \quad \mathrm{K}_{\text {sp }}=\left[\mathrm{Ca}^{2+}\right]^{3}\left[\mathrm{PO}_{4}{ }^{3-}\right]^{2}$
17.2 Calculate the molar solubility. Then, assemble the usual concentration table, and substitute the equilibrium concentrations from it into the equilibrium-constant expression. (Because no concentrations can be given for solid AgCl , dashes are written; in later problems, similar spaces will be left blank.)

$$
\frac{1.9 \times 10^{-3} \mathrm{~g}}{1 \mathrm{~L}} \times \frac{1 \mathrm{~mol}}{143 \mathrm{~g}}=\mathbf{1 . 3 3} \times 1 \mathbf{1 0}^{-5} \mathbf{M}
$$

Conc. (M) $\quad \mathbf{A g C l}(\mathrm{s}) \quad \leftarrow \rightarrow \mathbf{A g}^{+} \quad+\quad \mathrm{Cl}^{-}$
Starting
0
Set up the table as usual.

Change
$+1.33 \times 10^{-5} \quad+1.33 \times 10^{-5}$
Equilibrium
$1.33 \times 10^{-5}$
$1.33 \times 10^{-5}$
$K_{\text {sp }}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=\left(1.33 \times 10^{-5}\right)\left(1.33 \times 10^{-5}\right)=1.768 \times 10^{-10}=1.8 \times 10^{-10}$
17.3 Calculate the molar solubility. Then, assemble the usual concentration table and substitute from it into the equilibrium-constant expression. (Because no concentrations can be given for solid $\mathrm{Pb}_{3}\left(\mathrm{AsO}_{4}\right)_{2}$, spaces are left blank.)

$$
\frac{3.0 \times 10^{-5} \mathrm{~g}}{1 \mathrm{~L}} \times \frac{1 \mathrm{~mol}}{899 \mathrm{~g}}=3 . \underline{3} 4 \times 10^{-8} \mathrm{M}
$$

Conc. (M) $\quad \mathrm{Pb}_{3}\left(\mathrm{AsO}_{4}\right)_{2}(\mathrm{~s}) \leftarrow \rightarrow 3 \mathrm{~Pb}^{2+} \quad+2 \mathrm{AsO}_{4}{ }^{3-}$
Starting 00
Change $\quad+3\left(3.34 \times 10^{-8}\right) \quad+2\left(3.34 \times 10^{-8}\right)$
Equilibrium $\quad 3\left(3.34 \times 10^{-8}\right) 2\left(3.34 \times 10^{-8}\right)$
$\mathrm{K}_{\text {sp }}=\left[\mathrm{Pb}^{2+}\right]^{3}\left[\mathrm{AsO}_{4}{ }^{3-}\right]^{2}=\left[3 \times\left(3.34 \times 10^{-8}\right)\right]^{3}\left(2 \times 3.34 \times 10^{-8}\right)^{2}$
$=4.489 \times 10^{-36}=4.5 \times 10^{-36}$
17.4 Assemble the usual concentration table. Let $x$ equal the molar solubility of $\mathrm{CaSO}_{4}$. When x mol $\mathrm{CaSO}_{4}$ dissolves in one L of solution, $x \mathrm{~mol} \mathrm{Ca}^{2+}$ and $x \mathrm{~mol} \mathrm{SO} \mathbf{4}^{2-}$ form.

| Conc. $(\mathrm{M})$ | $\mathrm{CaSO}_{4}(\mathrm{~s})$ | $\leftarrow \rightarrow$ | $\mathrm{Ca}^{2+}$ | $+\mathrm{SO}_{4}{ }^{2-}$ |
| :--- | :--- | :--- | :--- | :--- |
| Starting |  |  | 0 | 0 |
| Change |  |  | $+\mathbf{x}$ | $+\mathbf{+ x}$ |
| Equilibrium |  |  | x | $\mathbf{x}$ |

Substitute the equilibrium concentrations into the equilibrium-constant expression and solve for $\mathbf{x}$. Then, convert to $\mathrm{g} \mathrm{CaSO}_{4}$ per L .

$$
\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]=\mathbf{K}_{\mathrm{sp}}
$$

$$
(x)(x)=x^{2}=2.4 \times 10^{-5}
$$

$$
\mathbf{x}=\sqrt{\left(2.4 \times 10^{-5}\right)}=4 . \underline{89} \times 10^{-3} \mathrm{M}
$$

$$
\frac{4.89 \times 10^{-3} \mathrm{~mol}}{\mathrm{~L}} \times \frac{136 \mathrm{~g}}{1 \mathrm{~mol}}=\mathbf{0 . 6 6 6 4}=\mathbf{0 . 6 7} \mathrm{g} / \mathrm{L}
$$

17.5 a. Let $x$ equal the molar solubility of $\mathrm{BaF}_{2}$. Assemble the usual concentration table, and substitute from the table into the equilibrium-constant expression.

Conc. (M) $\quad \mathrm{BaF}_{2}(\mathrm{~s})$
Starting
Change

| $\leftarrow \rightarrow$ | $\mathrm{Ba}^{2+}$ | + | $2 \mathbf{F}^{-}$ |
| ---: | :--- | ---: | :--- |
|  | $\mathbf{0}$ |  | 0 |
|  | $+\mathbf{x}$ |  | $+2 \mathbf{x}$ |
|  | $\mathbf{x}$ |  | $2 \mathbf{x}$ |

$$
\begin{aligned}
& \begin{array}{ll}
{\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}} & =\mathrm{K}_{\text {sp }} \\
(\mathrm{x})(2 \mathrm{x})^{2} & =4 \mathrm{x}^{3}=1.0 \times 10^{-6} \\
\mathbf{x}=\sqrt[3]{\frac{1.0 \times 10^{-6}}{4}}=6.299 \times 10^{-3}=6.3 \times 10^{-3} \mathrm{M}
\end{array}
\end{aligned}
$$

b. At the start, before any $\mathrm{BaF}_{2}$ dissolves, the solution contains 0.15 MF . At equilibrium, x mol of solid $\mathrm{BaF}_{2}$ dissolves to yield $\mathrm{x} \mathrm{mol} \mathrm{Ba}^{2+}$ and 2 x mol $\mathrm{F}^{-}$. Assemble the usual concentration table, and substitute the equilibrium concentrations into the equilibrium-constant expression. As an approximation, assume $x$ is negligible compared to $0.15 \mathrm{MF}^{-}$.

Note that adding 2 x to 0.15 M will not change it (to two significant figures), so 2 x is negligible compared to 0.15 M . The solubility of $4.4 \times 10^{-5} \mathrm{M}$ in 0.15 M NaF is lower than the solubility of $6.3 \times 10^{-3} \mathrm{M}$ in pure water.
17.6 Calculate the ion product, $Q_{c}$, after evaporation, assuming no precipitation has occurred.

Compare it with the $K_{\text {sp }}$.
$\mathbf{Q}_{\mathrm{c}}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]$
$\mathbf{Q}_{\mathrm{c}}=(\mathbf{2} \times 0.0052)(2 \times 0.0041)=8.528 \times 10^{-5}$
Since $Q_{c}>K_{\text {sp }}\left(2.4 \times 10^{-5}\right)$, precipitation occurs.
17.7 Calculate the concentrations of $\mathrm{Pb}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$, assuming no precipitation. Use a total volume of 0.456 L +0.255 L , or 0.711 L .
$\left[\mathrm{Pb}^{2+}\right]=\frac{\frac{0.00016 \mathrm{~mol}}{\mathrm{~L}} \times 0.255 \mathrm{~L}}{0.711 \mathrm{~L}}=5.74 \times 10^{-5} \mathrm{M}$
$\left[\mathrm{SO}_{4}{ }^{2-}\right]=\frac{\frac{0.00023 \mathrm{~mol}}{\mathrm{~L}} \times 0.456 \mathrm{~L}}{0.711 \mathrm{~L}}=1.48 \times 10^{-4} \mathrm{M}$
Calculate the ion product, and compare it to $\mathrm{K}_{\text {sp }}$.
$\mathrm{Q}_{\mathrm{c}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]=\left(5.74 \times 10^{-5}\right)\left(1.48 \times 10^{-4}\right)=8.49 \times 10^{-9}$
Because $\mathrm{Q}_{\mathrm{c}}$ is less than the $\mathrm{K}_{\text {sp }}$ of $1.7 \times 10^{-8}$, no precipitation occurs, and the solution is unsaturated.
17.8 The solubility of AgCN would increase as the pH decreases because the increasing concentration of $\mathrm{H}_{3} \mathrm{O}^{+}$would react with the $\mathrm{CN}^{-}$to form the weakly ionized acid HCN . As $\mathrm{CN}^{-}$is removed, more AgCN dissolves to replace the cyanide: In the case of AgCl , the chloride ion is the conjugate base of a strong acid and would, therefore, not be affected by any amount of hydrogen ion.

$$
\mathrm{AgCN}(\mathrm{~s}) \leftarrow \rightarrow \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{CN}^{-}(\mathrm{aq}) \quad\left[+\mathrm{H}_{3} \mathrm{O}^{+} \rightarrow \mathbf{H C N}+\mathrm{H}_{2} \mathrm{O}\right]
$$

17.9 Because $\mathrm{K}_{\mathrm{f}}=4.8 \times 10^{12}$ and because the starting concentration of $\mathrm{NH}_{3}$ is much larger than that of the $\mathrm{Cu}^{2+}$ ion, you can make a rough assumption that most of the copper(II) is converted to $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ ion. This ion then dissociates slightly to give a small concentration of $\mathrm{Cu}^{2+}$ and additional $\mathrm{NH}_{3}$. The amount of $\mathrm{NH}_{3}$ remaining at the start after reacting with $0.015 \mathrm{M} \mathrm{Cu}^{2+}$ is

## $[0.100 \mathrm{M}-(4 \times 0.015 \mathrm{M})]=\mathbf{0 . 0 4 0} \mathrm{M}$ starting $\mathrm{NH}_{3}$

Assemble the usual concentration table using this starting concentration for $\mathrm{NH}_{3}$ and assuming the starting concentration of $\mathrm{Cu}^{2+}$ is zero.

| Conc. (M) | $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ | $\leftarrow \rightarrow$ | $\mathrm{Cu}^{2+}$ | + |
| :--- | :--- | :--- | :--- | :--- |
| Starting | 0.015 |  | 0 | 0.040 |
| Change | -x |  | +x | +4 x |
| Equilibrium | $0.015-\mathrm{x}$ |  | x | $0.040+4 \mathrm{x}$ |

Even though this reaction is the opposite of the equation for the formation constant, the formation-constant expression can be used. Simply substitute all exact equilibrium concentrations into the formation-constant expression; then, simplify the exact equation by assuming x is negligible compared to 0.015 and 4 x is negligible compared to 0.040 .

$$
\mathrm{K}_{\mathrm{f}}=\frac{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}=\frac{(0.015-\mathrm{x})}{(\mathrm{x})(0.040+4 \mathrm{x})^{4}} \cong \frac{(0.015)}{(\mathrm{x})(0.040)^{4}} \cong 4.8 \times 10^{-12}
$$

Rearrange and solve for x :
$\mathrm{x}=\left[\mathrm{Cu}^{2+}\right] \cong(0.015) \div\left[\left(4.8 \times 10^{12}\right)(0.040)^{4}\right] \cong 1.22 \times 10^{-9}=1.2 \times 10^{-9} \mathrm{M}$
17.10 Start by calculating the $\left[\mathrm{Ag}^{+}\right]$in equilibrium with the $\mathrm{Ag}(\mathrm{CN})_{2}{ }^{-}$formed from $\mathrm{Ag}^{+}$and $\mathrm{CN}^{-}$. Then, use the $\left[\mathrm{Ag}^{+}\right]$to decide whether or not AgI will precipitate by calculating the ion product and comparing it with the $\mathrm{K}_{\text {sp }}$ of $8.3 \times 10^{-17}$ for AgI. Assume all the $0.0045 \mathrm{M} \mathrm{Ag}^{+}$reacts with $\mathrm{CN}^{-}$to form $0.0045 \mathrm{M} \mathrm{Ag}(\mathrm{CN})_{2}^{-}$, and calculate the remaining $\mathrm{CN}^{-}$. Use these as starting concentrations for the usual concentration table.
$[0.20 \mathrm{M} \mathrm{KCN}-(2 \times 0.0045 \mathrm{M})]=0.191 \mathrm{M}$ starting $\mathrm{CN}^{-}$

| Conc. (M) | $\mathrm{Ag}(\mathrm{CN})_{2}-$ | $\leftarrow \rightarrow$ | $\mathrm{Ag}^{+}$ | $+2 \mathrm{CN}^{-}$ |
| :---: | :--- | :---: | :---: | :---: |
| Starting | 0.0045 |  | 0 | 0.191 |
| Change | -x |  | +x | +2 x |
| Equilibrium | $0.0045-\mathrm{x}$ |  | x | $0.191+2 \mathrm{x}$ |

Even though this reaction is the opposite of the equation for the formation constant, the formationconstant expression can be used. Simply substitute all exact equilibrium concentrations into the formationconstant expression; then, simplify the exact equation by assuming x is negligible compared to 0.0045 and 2 x is negligible compared to 0.191 .
$\mathrm{K}_{\mathrm{f}}=\frac{\left[\mathrm{Ag}(\mathrm{CN})_{2}{ }^{-}\right]}{\left.\left[\mathrm{Ag}^{+}\right][\mathrm{CN}]^{-}\right]^{2}}=\frac{(0.0045-\mathrm{x})}{(\mathrm{x})(0.191+2 \mathrm{x})^{2}} \cong \frac{(0.0045)}{(\mathrm{x})(0.191)^{2}} \cong 5.6 \times 10^{18}$
Rearrange and solve for x :
$\mathrm{x}=\left[\mathrm{Ag}^{+}\right] \cong(0.0045) \div\left[\left(5.6 \times 10^{18}\right)(0.191)^{2}\right] \cong 2.202 \times 10^{-20} \mathrm{M}$
Now, calculate the ion product for AgI :
$\mathrm{Q}_{\mathrm{c}}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{I}^{-}\right]=\left(2.20 \times 10^{-20}\right)(0.15)=3.30 \times 10^{-21}=3.3 \times 10^{-21}$
Because $\mathrm{Q}_{\mathrm{c}}$ is less than the $\mathrm{K}_{\text {sp }}$ of $8.3 \times 10^{-17}$, no precipitate will form, and the solution is unsaturated.
17.11 Obtain the overall equilibrium constant for this reaction from the product of the individual equilibrium constants of the two individual equations whose sum gives this equation:
$\mathrm{AgBr}(\mathrm{s})$
$\leftarrow \rightarrow \mathrm{Ag}^{+}(\mathrm{aq}) \quad+\quad \mathrm{Br}^{-}(\mathrm{aq})$
$\mathrm{K}_{\text {sp }}=5.0 \times 10^{-13}$
$\mathrm{Ag}^{+}(\mathrm{aq})+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(\mathrm{aq}) \quad \leftarrow \rightarrow \mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(\mathrm{aq}) \quad \mathrm{K}_{\mathrm{f}}=2.9 \times 10^{13}$
$\mathrm{AgBr}(\mathrm{s})+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(\mathrm{aq}) \quad \leftarrow \rightarrow \mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}^{3-}(\mathrm{aq}) \quad+\mathrm{Br}^{-}(\mathrm{aq}) \quad \mathrm{K}_{\mathrm{c}}=\mathrm{K}_{\mathrm{sp}} \times \mathrm{K}_{\mathrm{f}}=14.5$

Assemble the usual table using 1.0 M as the starting concentration of $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ and x as the unknown concentration of $\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}$ formed.

| Conc. $(\mathrm{M}) \mathrm{AgBr}(\mathrm{s})$ | + | $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ | $\leftarrow \rightarrow$ | $\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}+$ |
| :--- | :--- | :--- | :--- | :--- |
| Starting | 1.0 | 0 | $\mathrm{Br}^{-}$ |  |
| Change | -2 x |  | +x | 0 |
| Equilibrium | $1.0-2 \mathrm{x}$ |  | x | +x |
|  |  |  |  |  |

The equilibrium-constant expression can now be used. Simply substitute all exact equilibrium concentrations into the equilibrium-constant expression. The solution can be obtained without using the quadratic equation.

$$
\mathrm{K}_{\mathrm{c}}=\frac{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right]\left[\mathrm{Br} r^{-}\right]}{\left[\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right]^{2}}=\frac{(\mathrm{x})^{2}}{(1.0-2 \mathrm{x})^{2}}=14.5
$$

Take the square root of both sides of the two right-hand terms, and solve for x :

$$
\begin{aligned}
& \frac{x}{(1.0-2 x)}=3.808 \\
& 7.62 \mathrm{x}+\mathrm{x}=3.808 \\
& x=0.4 \underline{417}=0.44 \mathrm{M} \text { (Molar solubility of } \mathrm{AgBr} \text { in } 1.0 \mathrm{M} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3} \text { ) }
\end{aligned}
$$

## - Answers to Concept Checks

17.1 Solubility and $K_{\text {sp }}$ are related, although not directly. You can compare $K_{\text {sp }}$ 's for a series of salts, however, if they have the same number of cations and anions in each of their formulas. (In that case, $\mathrm{K}_{\mathrm{sp}}$ and solubility are related in the same way for each salt.) In this problem, each of the lead(II) compounds has one $\mathrm{Pb}^{2+}$ cation and one anion, so you can compare the $\mathrm{K}_{\text {sp }}$ 's directly.
Lead(II) sulfate has the largest $K_{\text {sp }}$ and, therefore, is the most soluble of these lead(II) compounds.
17.2 Let's look at each compound in turn.
$\mathrm{NaNO}_{3}$ has no ion in common with $\mathrm{PbSO}_{4}$, so it should have little effect on its solubility.
$\mathrm{Na}_{2} \mathrm{SO}_{4}$ is a soluble compound and provides the common ion $\mathrm{SO}_{4}{ }^{2-}$, which would repress the solubility of $\mathrm{PbSO}_{4}$.
PbS has an ion in common with $\mathrm{PbSO}_{4}\left(\mathrm{~Pb}^{2+}\right)$, but the compound is so insoluble that very little of the $\mathrm{Pb}^{2+}$ ion is available.
Because of this, the solubility of $\mathrm{PbSO}_{4}$ is little affected by the PbS . Therefore, the $\mathrm{NaNO}_{3}$ solution will dissolve the most $\mathrm{PbSO}_{4}$.
17.3 If NaCl were added to a saturated AgCl solution, the equilibrium would shift to consume the added chloride ion, and some AgCl would precipitate. After the addition of two $\mathrm{Cl}^{-}$ions, there would be five $\mathrm{Cl}^{-}$ions, three $\mathrm{Ag}^{+}$ions, and two AgCl molecules. The solution would look like the following ( $\mathrm{Na}^{+}$not shown for clarity).

17.4 If you compare $\mathrm{K}_{\text {sp }}$ 's for magnesium oxalate ( $8.5 \times 10^{-5}$ ) and calcium oxalate ( $2.3 \times 10^{-9}$ ), you can see magnesium oxalate is much more soluble in water solution than the calcium salt (the $\mathrm{K}_{\mathrm{sp}}$ is larger). This means it provides a greater concentration of oxalate ion. In water solution, some of the magnesium oxalate dissolves, giving an oxalate ion concentration that tends to repress the dissolution of calcium oxalate (common-ion effect). The addition of acid tends to remove oxalate ion, but this is replenished by the dissolution of more magnesium oxalate. Therefore, you would expect the magnesium oxalate to be more likely to dissolve.
